STUDIES RELATED TO WILDERNESS

Bureau of Land Management Wilderness Study Areas

The Federal Land Policy and Management Act (Public Law 94-579, October 21, 1976) requires the U.S. Geological Survey and the U.S. Bureau of Mines to conduct mineral surveys on certain areas to determine their mineral values, if any. Results must be made available to the public and be submitted to the President and the Congress. This report presents the results of geochemical surveys of the Little Jacks Creek (ID-111-06), Big Jacks Creek (ID-111-07C), Duncan Creek (ID-111-07B), and the Upper Deep Creek (ID-111-44) Bureau of Land Management Wilderness Study Areas, Owyhee County, Idaho.

INTRODUCTION

In July 1985, the U.S. Geological Survey conducted reconnaissance geochemical surveys of the Little Jacks Creek (ID-111-06), Big Jacks Creek (ID-111-07C), Duncan Creek (ID-111-07B), and Upper Deep Creek (ID-111-44) Bureau of Land Management Wilderness Study Area, Owyhee County, Idaho.

Bureau of Land Management Wilderness Study Areas in Owyhee County, Idaho covered in this report are:

Wilderness Study Area	SIZE		
	Mi ²	Km ²	Acres
Little Jacks Creek	53	138	34,000
Big Jacks Creek	78	203	49,875
Duncan Creek	15	39	9,400
Upper Deep Creek	9	23	5,700

The Little Jacks Creek, Big Jacks Creek, and Duncan Creek Wilderness Study Areas are contiguous areas west of State Highway 51 in the western half of Owyhee County, southwestern Idaho, and lie about 31 mi (50 km) southwest of Mountain Home, Idaho (fig. 1). The Upper Deep Creek Wilderness Study Area lies about 24 mi (38 km) west of those areas (fig. 2). Access to the Little Jacks Creek and Big Jacks Creek Wilderness Study Areas is provided on the north by an improved light duty road that connects with State Highway 78 near Grandview, Idaho. This road continues to the southwest to near the Upper Deep Creek Wilderness Study Area. Access to the Duncan Creek and eastern parts of the Little Jacks Creek and Big Jacks Creek Wilderness Study Areas is provided by several unimproved dirt roads that connect to State Highway 51. Further access to all areas may be by additional unimproved dirt roads and by jeep trails.

The study areas are located on the Owyhee Upland, an extensive volcanic plateau south of the western Snake River Plain. The areas are underlain by Miocene rhyolitic rocks locally covered by a thin veneer of basalt. The rock units are described in detail in Ekren and others (1984). The geologic map of Owyhee County, Idaho, west of longitude 116°W. (Ekren and others, 1981) includes these study areas.

The ground surface of the Upper Deep Creek study area slopes gently southward from a maximum elevation of 5,760 ft (1,756 m) at the northern end down to 4,800 ft (1,463 m) along Upper Deep Creek at the southern end. Topographic relief in the Duncan Creek, Little Jacks Creek, and Big Jacks

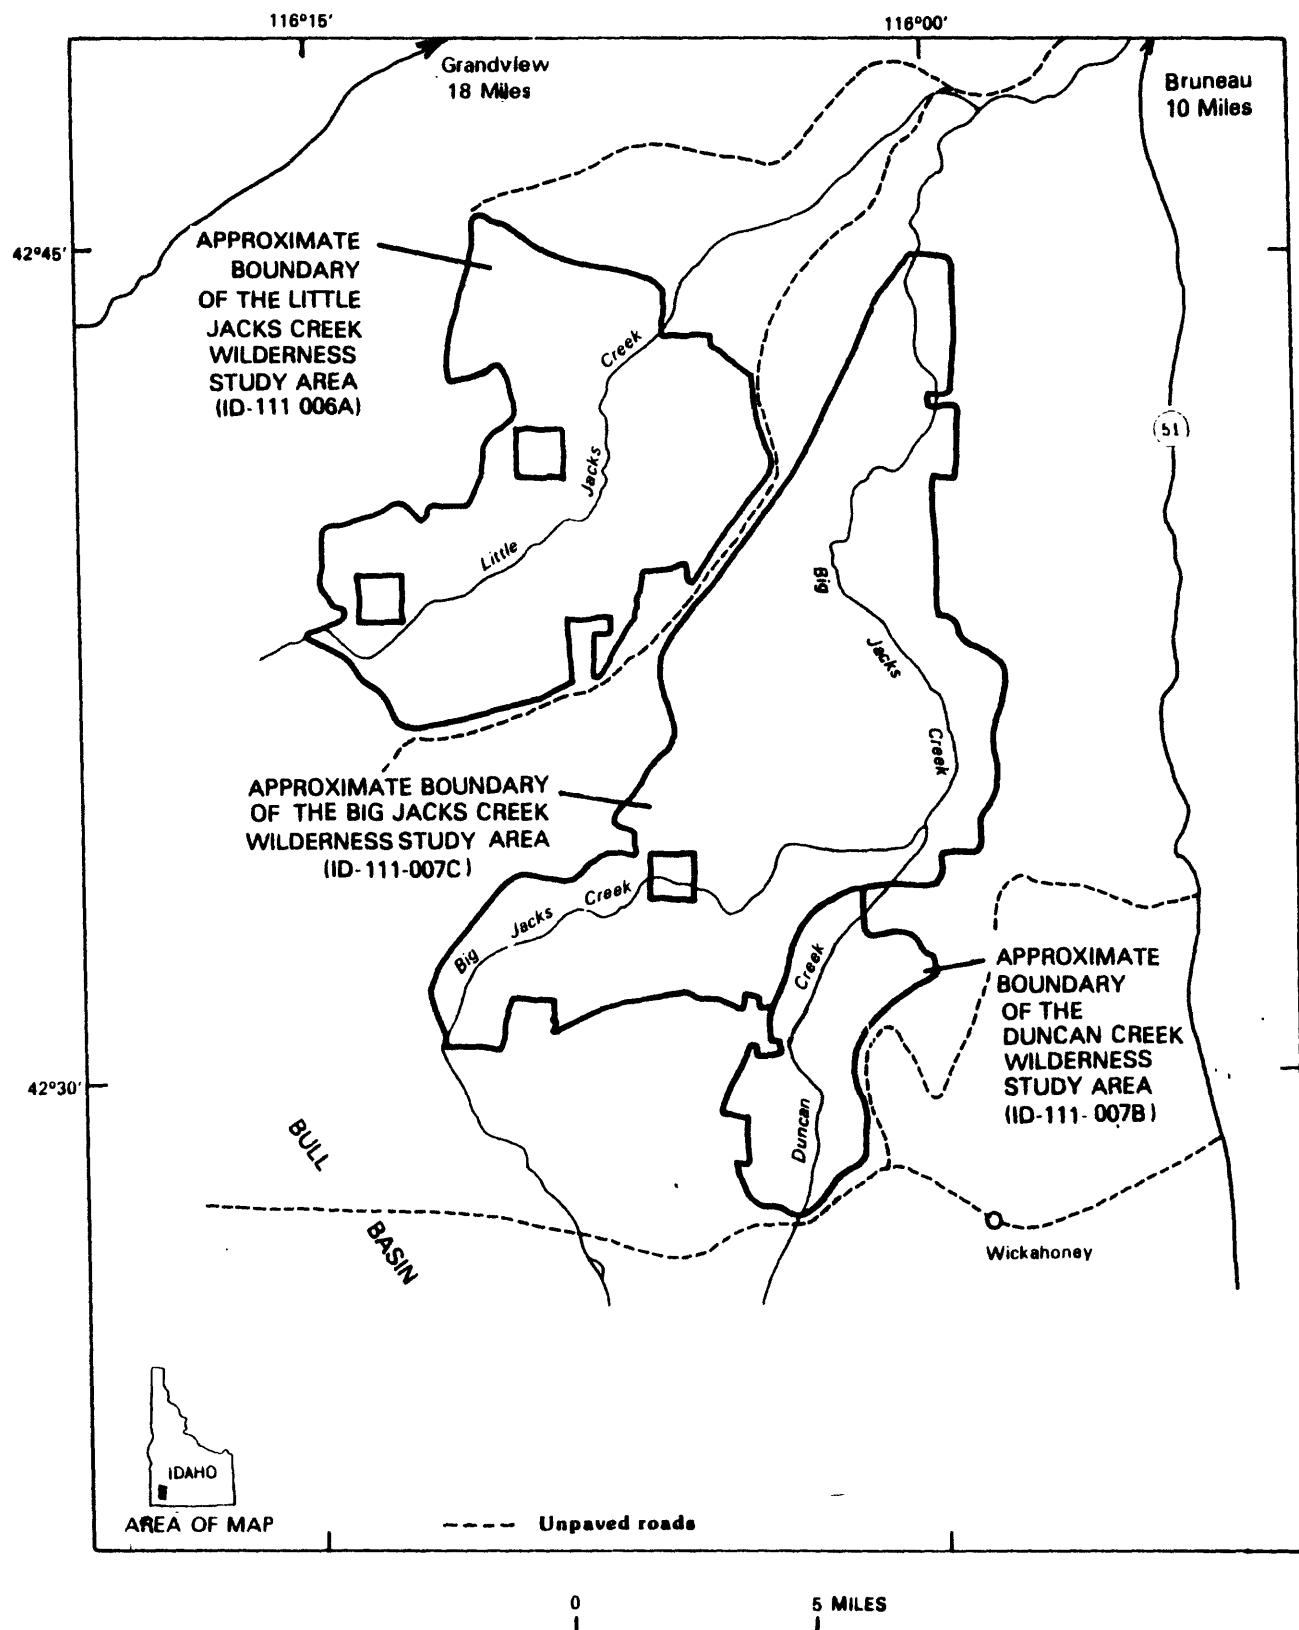

Figure 1. Index map showing locations of the Little Jacks Creek, Big Jacks Creek, and Duncan Creek Wilderness Study Areas, Owyhee County, Idaho.

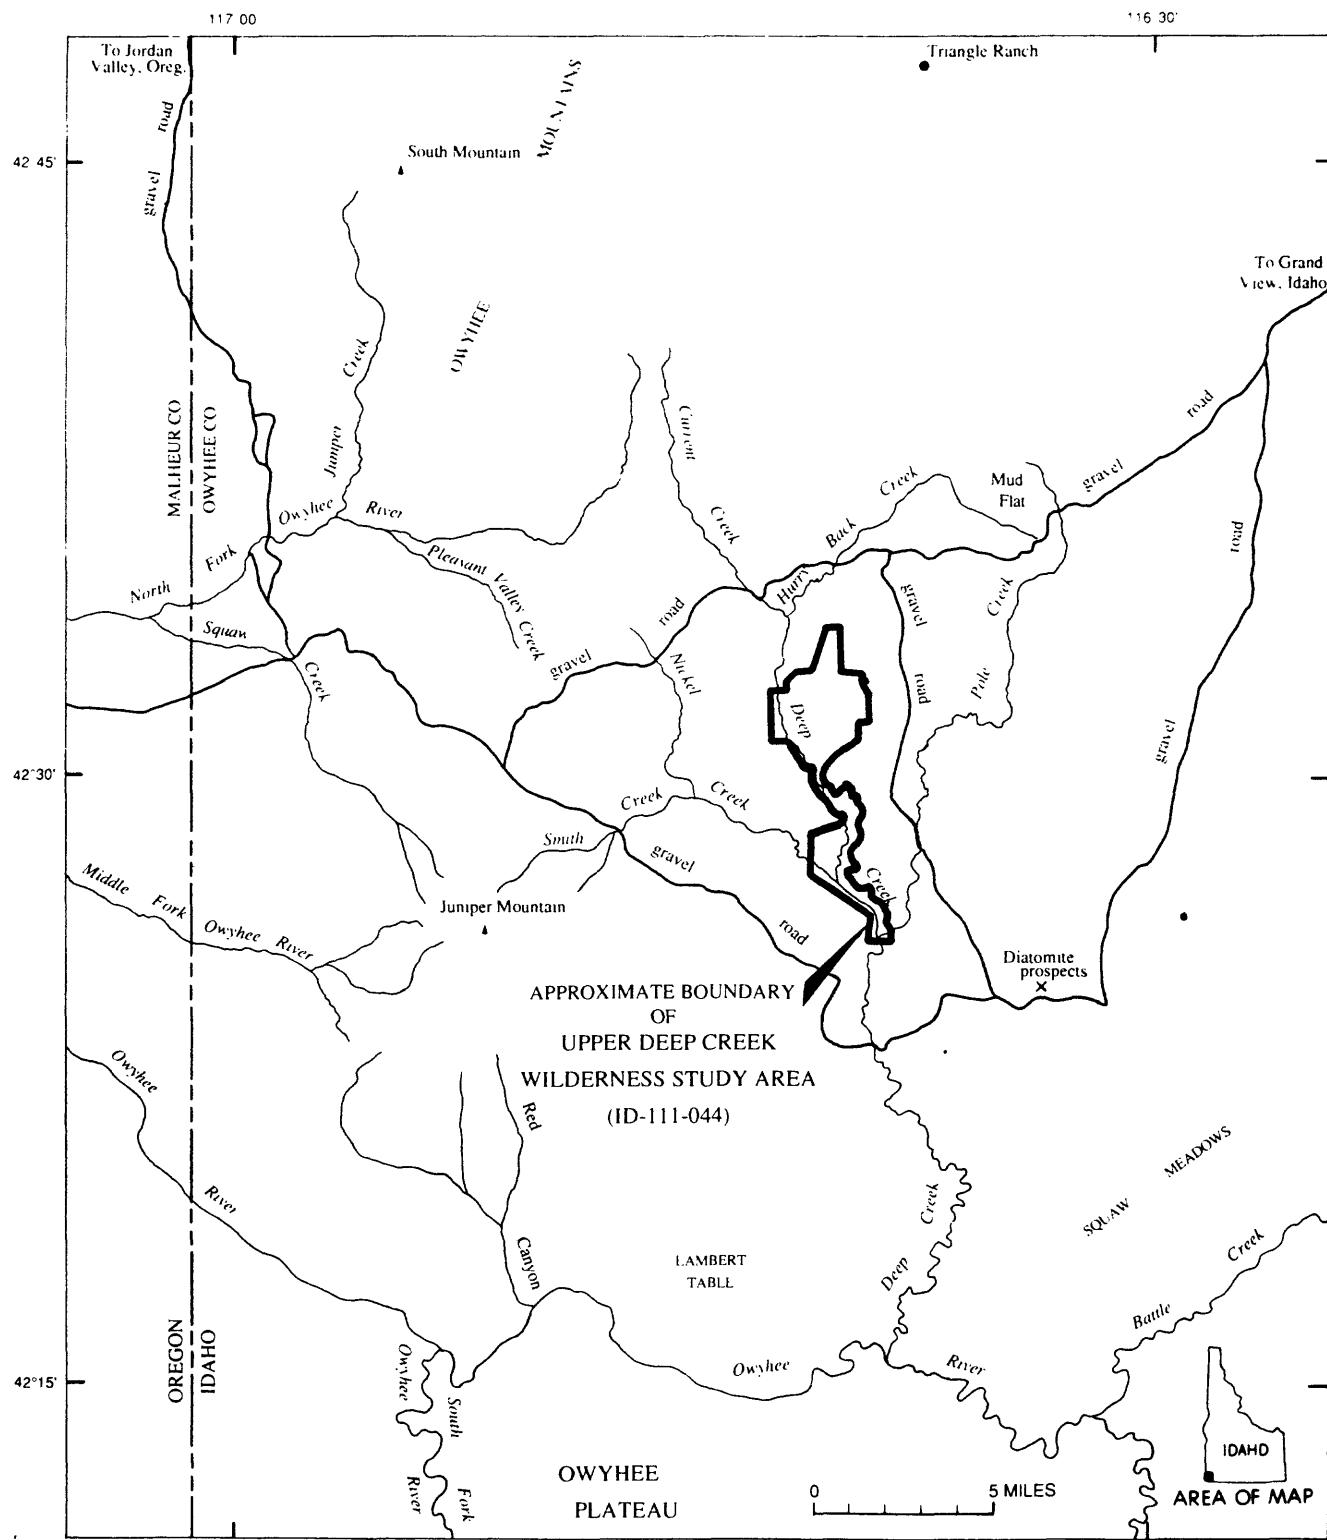

Figure 2. Index map showing location of Upper Deep Creek Wilderness Study Area, Owyhee County, Idaho.

Creek study areas is about 1,300 ft (396 m), 2,300 ft (701 m), and 2,900 ft (884 m), respectfully. These areas have maximum elevations close to 5,900 ft (1,798 m). Canyons cut by Little Jacks, Big Jacks, and Duncan Creeks are steep and rugged with heights of about 800 ft (244 m) along Little Jacks and Big Jacks Creeks and about 500 ft (152 m) along Duncan Creek. Valley sides along Upper Deep Creek are relatively less rugged and are generally about 400 ft (122 m) in height. The climate is arid to semiarid.

METHODS OF STUDY

Sample Media

Analyses of the stream-sediment samples represent the chemistry of the rock material eroded from the drainage basin upstream from each sample site. Such information is useful in identifying those basins which contain concentrations of elements that may be related to mineral deposits. Heavy-mineral-concentrate samples provide information about the chemistry of certain minerals in rock material eroded from the drainage basin upstream from each sample site. The selective concentration of minerals, many of which may be ore related, permits determination of some elements that are not easily detected in stream-sediment samples.

Analyses of unaltered or unmineralized rock samples provide background geochemical data for individual rock units. On the other hand, analyses of altered or mineralized rocks, where present, may provide useful geochemical information about the major- and trace-element assemblages associated with a mineralizing system.

Sample Collection

Samples were collected at 182 sites (table 1; plates 1 and 2). At nearly all of those sites, both a stream-sediment sample and a heavy-mineral-concentrate sample were collected. Where suitable outcrop was available, rock samples were collected. Average sampling density was about one sample site per .9 mi² for the stream sediments and heavy-mineral concentrates, and about one sample site per 5 mi² for the rocks. The area of the drainage basins sampled ranged from .5 mi² to 2 mi².

TABLE 1.--Number of sample sites for each Wilderness Study Area

Wilderness Study Area	Number of Sites
Little Jacks Creek	59
Big Jacks Creek	81
Duncan Creek	17
Upper Deep Creek	25

Stream-sediment samples

The stream-sediment samples consisted of active alluvium collected primarily from first-order (unbranched) and second-order (below the junction of two first-order) streams as shown on USGS topographic maps (scale = 1:24,000). Each sample was composited from several localities within an area that may extend as much as 20 ft from the site plotted on the map.

Heavy-mineral-concentrate samples

Heavy-mineral-concentrate samples were collected from the same active alluvium as the stream-sediment samples. Each bulk sample was screened with a 2.0-mm (10-mesh) screen to remove the coarse material. The less than 2.0-mm fraction was panned until most of the quartz, feldspar, organic material, and clay-sized material were removed.

Rock samples

Rock samples were collected from outcrops or exposures in the vicinity of the plotted site location. Samples were collected from unaltered and/or altered and/or mineralized rocks.

Sample Preparation

The stream-sediment samples were air dried, then sieved using 80-mesh (0.17-mm) stainless-steel sieves. The portion of the sediment passing through the sieve was saved for analysis.

After air drying, bromoform (specific gravity 2.8) was used to remove the remaining quartz and feldspar from the heavy-mineral-concentrate samples that had been panned in the field. The resultant heavy-mineral sample was separated into three fractions using a large electromagnet (in this case a modified Frantz Isodynamic Separator). The most magnetic material, primarily magnetite, was not analyzed. The second fraction, largely ferromagnesian silicates and iron oxides, was saved for archival storage. The third fraction (the least magnetic material which may include the nonmagnetic ore minerals, zircon, sphene, etc.) was split using a Jones splitter. One split was hand ground for spectrographic analysis; the other split was saved for mineralogical analysis. These magnetic separates are the same separates that would be produced by using a Frantz Isodynamic Separator set at a slope of 15° and a tilt of 10° with a current of 0.2 ampere to remove the magnetite and ilmenite, and a current of 0.6 ampere to split the remainder of the sample into paramagnetic and nonmagnetic fractions.

Rock samples were crushed and then pulverized to minus 0.15 mm with ceramic plates.

Sample Analysis

Spectrographic method

The stream-sediment, heavy-mineral-concentrate, and rock samples were analyzed for 31 elements using semiquantitative, direct-current arc emission spectrographic methods. The analyses of heavy-mineral-concentrate samples were performed by analysts in the Branch of Exploration Geochemistry using the method of the Grimes and Marranzino (1968); analyses for stream-sediment and rock samples were performed by analysts in the Branch of Analytical Chemistry

using a modification of the Myers and others method (1961) by Crock and others (1987). The elements analyzed and their lower limits of determination are listed in table 2. For arsenic (As), gold (Au), cadmium (Cd), lanthanum (La), and thorium (Th), the lower limit of determination of the two analytical methods varies. The values in the parentheses are the limits of determination for Myers and others (1961). Spectrographic results were obtained by visual comparison of spectra derived from the sample against spectra obtained from standards made from pure oxides and carbonates. Standard concentrations are geometrically spaced over any given order of magnitude of concentration as follows: 100, 50, 20, 10, and so forth. Samples whose concentrations are estimated to fall between those values are assigned values of 70, 30, 15, and so forth. The precision of the analytical method is approximately plus or minus one reporting interval at the 83 percent confidence level and plus or minus two reporting intervals at the 96 percent confidence level (Motooka and Grimes, 1976). Values determined for the major elements (iron, magnesium, calcium, and titanium) are given in weight percent; all others are given in parts per million (micrograms/gram). Analytical data for samples from the study areas discussed in this report are listed in tables 4-15.

Chemical methods

Other methods of analysis used on samples from the Little Jacks Creek, Big Jacks Creek, Duncan Creek, and Upper Deep Creek Wilderness Study Areas are summarized in table 3.

ROCK ANALYSIS STORAGE SYSTEM

Upon completion of all analytical work, the analytical results were entered into a computer-based file called Rock Analysis Storage System (RASS). This data base contains both descriptive geological information and analytical data. Any or all of this information may be retrieved and converted to a binary form (STATPAC) for computerized statistical analysis or publication (VanTrump and Miesch, 1977).

DESCRIPTION OF DATA TABLES

Tables 4-15 list the results of analyses for the stream-sediment, heavy-mineral concentrate, and rock samples for each of the four areas, respectively. For the tables, the data are arranged so that column 1 contains the USGS-assigned sample numbers. These numbers correspond to the numbers shown on the site location maps (plates 1 and 2). Columns in which the element headings show the letter "s" below the element symbol are emission spectrographic analyses; "aa" indicates atomic absorption analyses; "icp" indicates inductively coupled plasma-atomic emission spectroscopy. A letter "N" in the tables indicates that a given element was looked for but not detected at the lower limit of determination shown for that element in table 2. For emission spectrographic analyses, a "less than" symbol (<) entered in the tables in front of the lower limit of determination indicates that an element was observed but was below the lowest reporting value. For AA and ICP analyses, a "less than" symbol (<) entered in the tables in front of the lower limit of determination indicates that an element was below the lowest reporting value. If an element was observed but was above the highest reporting value, a "greater than" symbol (>) was entered in the tables in front of the upper limit of determination. If an element was not looked for

in a sample, two dashes (--) are entered in place of an analytical value. Because of the formatting used in the computer program that produced tables 4-15, some of the elements listed in these tables (Fe, Mg, Ca, Ti, Ag, and Be) carry one or more nonsignificant digits to the right of the significant digits. The analysts did not determine these elements to the accuracy suggested by the extra zeros.

ACKNOWLEDGMENTS

A number of our colleagues also participated in the collection, analysis, and preparation of these samples: collection, David McIntyre and Scott Minor; analysis and preparation, M.J. Malcolm, J.G. Crock, T. McCollum, and D. Fey. Mary Lou Tompkins compiled and retrieved all of the computer data.

TABLE 2.--Limits of determination for the spectrographic analysis of rocks and stream sediments, based on a 10-mg sample

[The values shown are the lower limits of determination assigned by the Grimes and Marranzino method, except for those values in parentheses, which are the lower values assigned by the Myers and others method. The spectrographic limits of determination for heavy-mineral-concentrate samples are based on a 5-mg sample, and are therefore two reporting intervals higher than the limits given for rocks.]

Elements	Lower determination limit	Upper determination limit
Percent		
Iron (Fe)	0.05	20
Magnesium (Mg)	.02	10
Calcium (Ca)	.05	20
Titanium (Ti)	.002	1
Parts per million		
Manganese (Mn)	10	5,000
Silver (Ag)	0.5	5,000
Arsenic (As)	200	(700)
